

Software Configuration Management Plan

Saketh S Tandige – 2023BCSE07AED498

CSE General

1. Introduction

The Software Configuration Management Plan (SCMP) defines the activities, roles, and procedures used to manage and control changes in the E-Book Management System project. It ensures that all software artifacts are properly identified, versioned, tracked, and maintained throughout the software development life cycle.

SCM helps maintain product integrity, improves collaboration, and reduces errors caused by uncontrolled changes.

2. Configuration Identification

Configuration Identification involves identifying and labelling all configuration items (CIs) produced during the project.

Configuration Items include:

- Source code files (Frontend and Backend)
- Database scripts and schemas
- Software Requirement Specification (SRS)
- Design documents (Architecture, ER diagrams, DFDs)
- Test cases and test reports
- User manuals and project documentation

3. Configuration Control

Configuration Control defines the process for managing changes to configuration items.

- All change requests must be formally documented
- Changes are reviewed by the project guide or team lead
- Only approved changes are implemented
- This process prevents unauthorized or accidental modifications

4. Configuration Status Accounting

Configuration Status Accounting is used to record and report the status of configuration items.

- Tracks current versions of all documents and code
- Maintains change history and approval records
- Provides reports on implemented and pending changes
- Ensures transparency and accountability in project development

5. Configuration Audits

Configuration Audits verify that configuration items are correct and complete.

- Confirms that approved changes are properly implemented
- Ensures consistency between documents and software
- Verifies version accuracy and completeness
- Helps identify missing or incorrect configuration items
